03: CONTROL STRUCTURES

Programming Technique I

(SECJ1013)

Boolean and Logical Operator

- In C++ logical data declared as `bool` data type

  e.g.
  ```
  bool variable_name;
  ```

- There are only two values: `true` and `false`

- Type-casting `bool` to `int`:

  - `true => 1`
  - `false => 0`

  Example

  ```
  int number;
  number = 2 + true;
  cout << number; //output: 3
  ```

Boolean and Logical Operator

- Type-casting **int** to **bool**:
  - A *Zero value* => **false**
  - A *Non-Zero value* => **true**

Example:

```
bool b = false;      // b initially is false
int number = 0;
b = -10;             // Now, b is true
b = number;          // Here, b is false again
```

Boolean and Logical Operator

What would be printed by this code segment

```
bool b;
int p;
int q = 5;

b = q;
p = b;
cout << "The value of p is " << p << endl;
```

Logical operators truth table

not

x	!x
false	true
true	false

logical

!

x	!x
zero	1
nonzero	0

C Language

and

x	y	x&&y
false	false	false
false	true	false
true	false	false
true	true	true

logical

&&

x	y	x&&y
zero	zero	0
zero	nonzero	0
nonzero	zero	0
nonzero	nonzero	1

C Language

or

x	y	x||y
false	false	false
false	true	true
true	false	true
true	true	true

logical

||

x	y	x||y
zero	zero	0
zero	nonzero	1
nonzero	zero	1
nonzero	nonzero	1

C Language

Operations for logical and/or

```
false && (anything)
```

↓

false

```
true || (anything)
```

↓

true

Relational operators

Operator	Meaning
<	less than
<=	less than or equal
>	greater than
>=	greater than or equal
==	equal
!=	not equal

Logical expression

Example:

```
int a=10;

cout << a;
cout << (a==1);   0
cout << (a>1);
cout << (a=5);

a = (a != 5);
out << a;
```
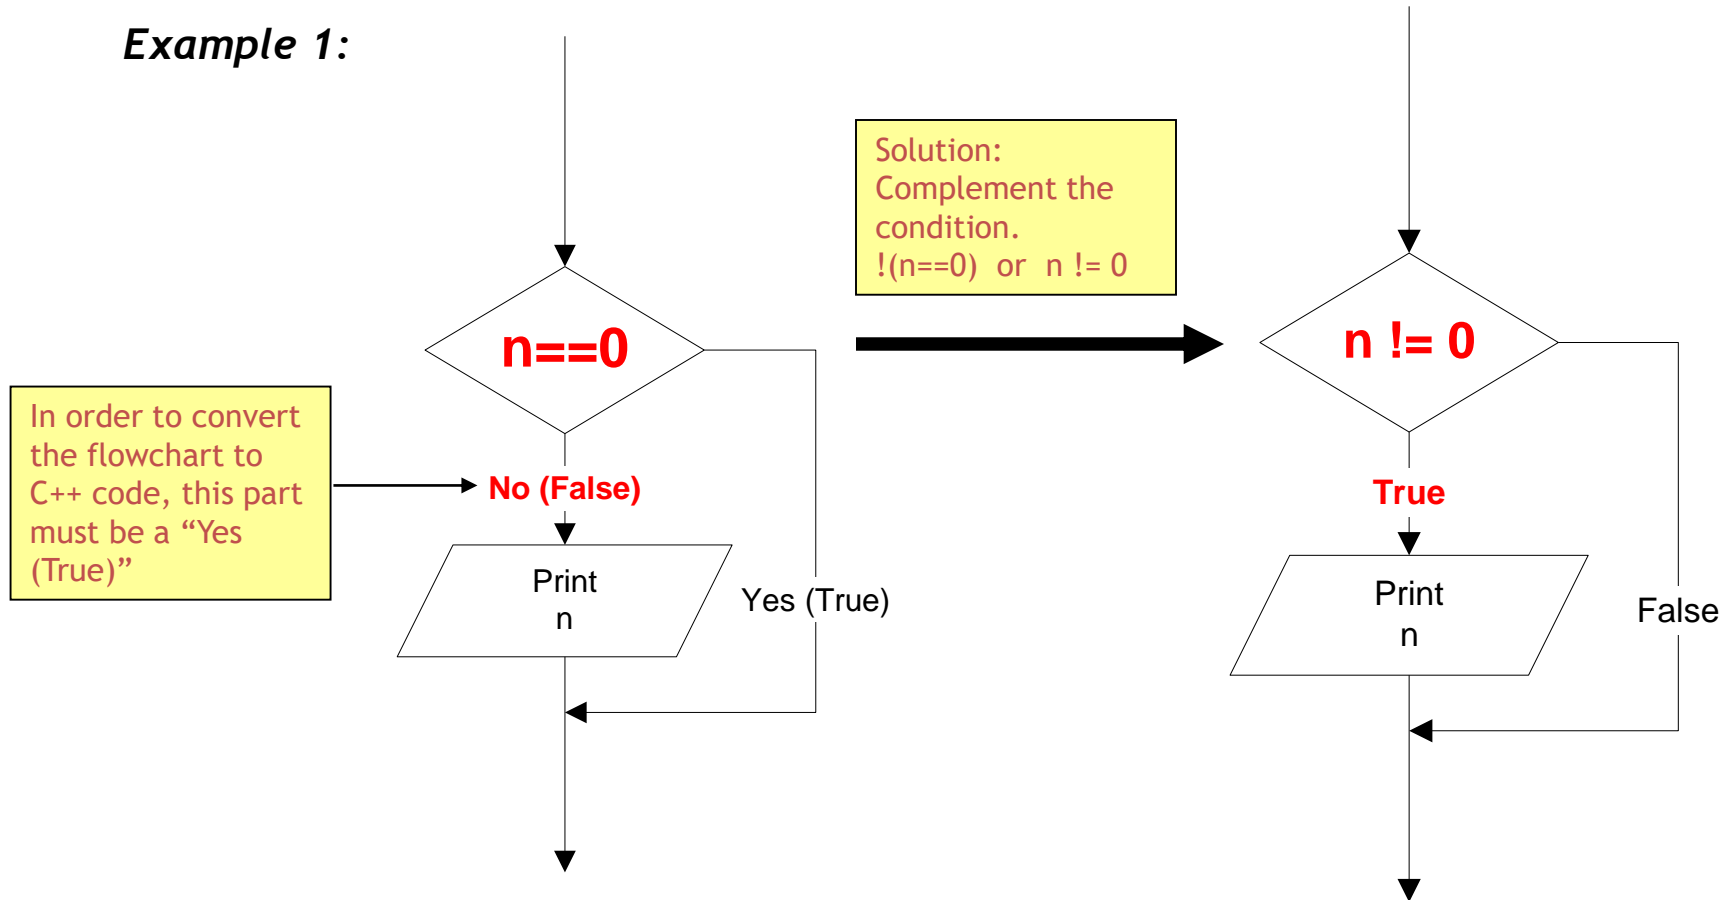

Logical operator complements
- **Another way to complement an expression is just putting a Not operator (!) in front of it.**

    Example: Complement of n==0 is
   ! (n==0)

- **When to use complement?**

Example 1:

Solution:
Complement the condition.
!(n==0) or n != 0

n==0

In order to convert the flowchart to C++ code, this part must be a "Yes (True)"

No (False)

Print
n

Yes (True)

n != 0

True

Print
n

False

When to use complement?

Example 2:

number = 10

Print

number

number = number -1

number< 1

True

False

The iteration part must be a True

Solution:
Complement the condition.
!(number<1) or
(number >=1)

number = 10

Print

number

number = number -1

number >= 1

False

True

Selection / Branch

- Sometimes your programs need to make logical choices.
- Example:

 **IF** score is higher than 50

  THEN grade is PASS

  ELSE grade is FAIL

- In C++, this corresponds to `if` statement with three parts:

```cpp
if (score > 50)   //part 1
{
    grade  = PASS;   //part 2
}
else
{
    grade = FAIL;   //part 3
}
```

`if` statement

- Part 1 : the **condition** - an expression that evaluates to `true` or `false`.

```
if (score > 50)
{
    grade  = PASS;
}
else
{
    grade = FAIL;
}
```

score > 50 —Yes→ grade = PASS

No ↓ grade = FAIL

`if` statement

- Part 2 : the **TRUE-PART** - a block of statements that are executed if the condition evaluates to `true`

```
if (score > 50)
 {
      grade  = PASS;
 }
else
 {
     grade = FAIL;
 }
```
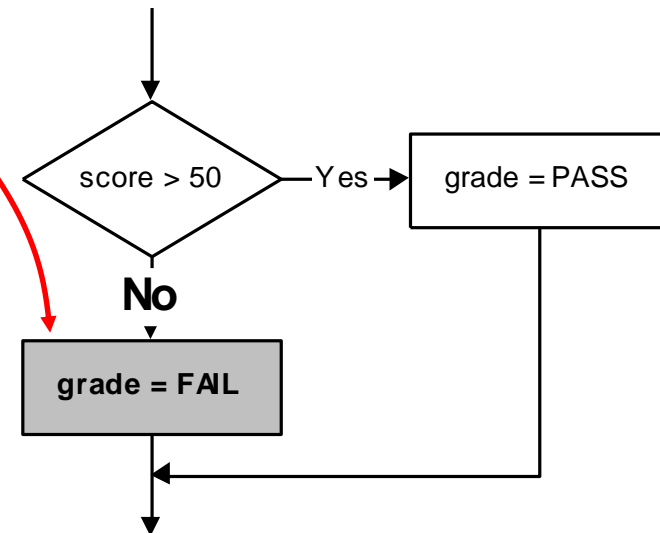

`if` statement

- Part 3 : the **FALSE-PART** - a block of statements that are executed if the condition evaluates to **false**

```
if (score > 50)
{
    grade = PASS;
}
else
{
    grade  = FAIL;
}
```
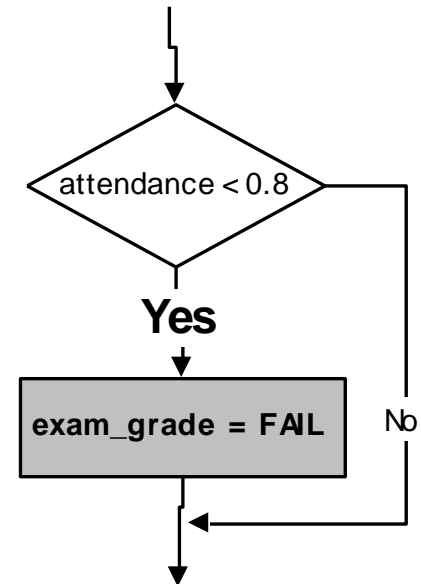

if the condition
evaluates to `false`,
the TRUE-PART is skipped.

if statement

- Sometimes there is no FALSE-PART. The "**else**" is omitted

```
if ( attendance < 0.8 )
{
    exam_grade = FAIL;
}
```

attendance < 0.8

Yes

exam_grade = FAIL

No

if statement

- If the TRUE-PART (or FALSE-PART) consists of only one statement, then the curly braces may be omitted.
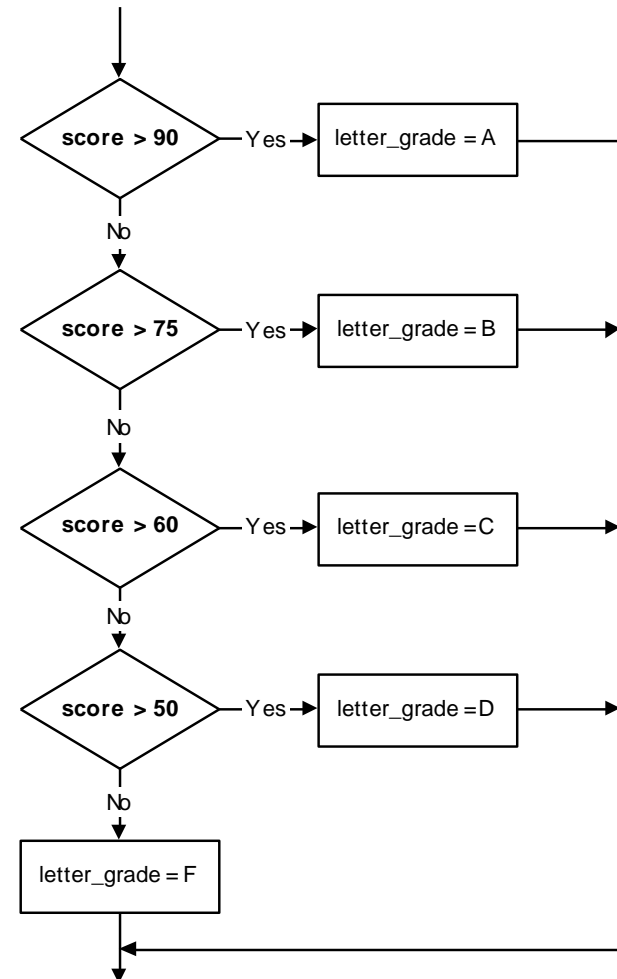

- *Example: these two statements are equivalent:*

```
if (score > 50)
{
   grade  = PASS;
}
else
{
   grade = FAIL;
}
```

```
if (score > 50)
       grade  = PASS;
else
       grade = FAIL;
```
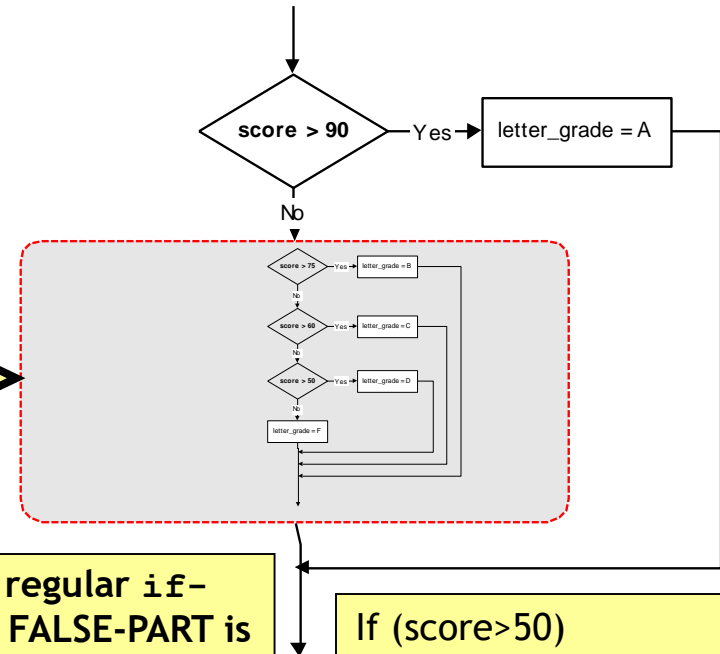

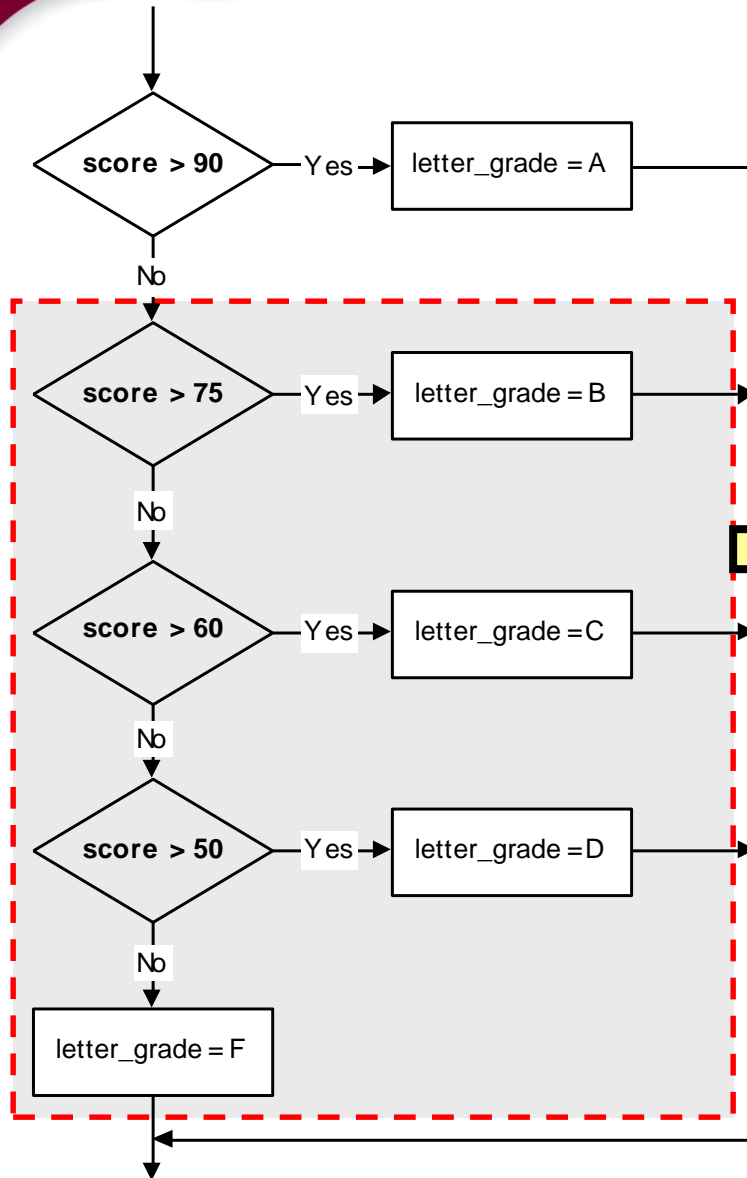

if statement

- Sometimes there are more than two parts. In those cases you may use nested **if-else** statements:

```
if (score > 90)
        letter_grade  = 'A';
else if (score > 75)
        letter_grade = 'B';
else if (score > 60)
        letter_grade = 'C';
else if (score > 50)
        letter_grade = 'D';
else
        letter_grade = 'F';
```

Let's look closer

score > 90 — Yes → letter_grade = A

No

score > 75 — Yes → letter_grade = B

No

score > 60 — Yes → letter_grade = C

No

score > 50 — Yes → letter_grade = D

No

letter_grade = F

score > 90 — Yes → letter_grade = A

No

It is actually a regular `if-else` with the FALSE-PART is another `if-else` statement

```
If (score>50)
{
    letter_grade = 'A';
}
else {
    ……..
    …….
}
```

if statement

- Three forms of `if` statements are shown at the next table.

- The *condition must be placed* in parentheses

- Statement may exist either as a single statement or as a collection of statements (also called compound statement)

```
if(condition)
    statement;
```

```
if (condition)
{ statement;
      |
   statement;
}
```

```
if (condition)
{ statement;
      |
   statement;
}
else
{ statement;
      |
   statement;
}
```

- A **compound statement** is one or more statements that are grouped together by enclosing them in brackets , { }.

- **Example:**

```
if (value > 0)
    cout << value;
```
This is a single statement. The semi-colon belongs to "if" not to "cout"

```
value = value * 2;
```
a single statement

```
if (value > 10)
{

    value = 10;
    cout << value;

}
```
This is a compound statement which consists two single statements.

Related issues

- The condition must be placed in parentheses

Example:

```
if ((0<x) && (x<10))    //syntax error
    cout << x;
```

Correction:

Related issues

- But be careful when converting mathematical comparisons. Some of them are not straight forward

Example: Print x only if (2<x<9)

```
if (2 < x < 9)
    cout << x;
```

There is no syntax error, but this leads to a **logic error** due to the misinterpretation.

The condition **always evaluates to true**, whatever the value of x

Let say x=1
(2<x<9)
⟹(2<1<9)
⟹(false<9)
⟹(0<9)
⟹true

Let say x=5
(2<x<9)
⟹(2<5<9)
⟹(true<9)
⟹(1<9)
⟹true

Correction:

Related issues

- The condition must evaluate to a Boolean value (i.e. either `true` or `false`)

- There are only two types of expression that result a Boolean value
  - Comparison expression (e.g. `a>2`)
  - Boolean expression (e.g. `b && false`)

- If the result of the condition is not a Boolean, it will be type-casted

> The condition evaluates to **0.** It then is type-casted to Boolean, becomes `false`

Example:

```
int n=0;

if (n)
    cout << "Yes";
else
    cout << "No";
```

Output:

Example:

The condition evaluates to **5.** It then is type-casted to Boolean, becomes **true**

```
int n=0;

if (n + 5)
    cout << "Yes";
else
    cout << "No";
```
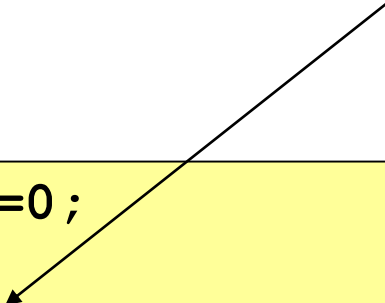

Output:

Example:

Remember! This is an **assignment expression**, not an equality.

The value of the expression is 0. It then is type-casted to Boolean, becomes `false`. The result is always false.

```
int x=0;

if (x=0)
    cout << "Yes";
else
    cout << "No";
```

Output:

Example:

Remember! This is an **assignment expression**, not an equality.

The value of the expression is $10.$ It then is type-casted to Boolean, becomes `true`. The result is always true.

```
int y=5;

if (y=10)
    cout << "Yes";
else
    cout << "No";
```

Output:

Example:

Remember! This is an **assignment expression.**

The condition always evaluates to `true`. The value of `y` is changed to `5` due to the side-effect caused by the assignment operator

```
int y=1;

if (y=5)
    cout << y;
```

Output:

Related issues

- Be careful when using the Boolean operator NOT (**!**)

  Example:

  ```
  int n=5;

  if (!n>9)
      cout << "Yes";
  else
      cout << "No";
  ```

  Operator **!** has higher precedence then operator **>**. So, it is executed first.

  Expression **!n** is evaluated as **!true** where n is type-casted from `integer` 5 to `Boolean true`. The result is **false**

  The expression is further evaluated as **(false>9)**. The false value is then type-casted to 0, since it will be compared with an integer. The expression then looks like **(0 > 9)** and the final result is **false**

  Output:

Example:

```
int n=5;

if (!(n>9))
    cout << "Yes";
else
    cout << "No";
```

```
(!(n>9))
⇒ (!(n>9))
⇒ (!(5>9))
⇒ (!(false))
⇒ (!false)
⇒ true
```

Output:

Related issues

- Statements should be indented correctly to avoid misinterpretations

Example:

```
if (x<3)
    cout <<"Yes" << endl;
    cout <<"No" << endl;
```

The second `cout` doesn't belong to `if` statement. It is on its own but was indented incorrectly.

Let say x=1,
Condition => true

Output:

Let say x=3
Condition => false

Output:

Correction:

```
if (x<3)
    cout <<"Yes" << endl;

cout <<"No" << endl;
```

Example:

```
if (x<y)
    cout << x;
    x = y;
else
    cout << y;
```

Syntax error – misplace else.
There must only be a single statement before `else`. If more than that, use a compound statement.

Correction:

Example:

Print x only if it is an odd number less than 10, otherwise print "Wrong number"

```
if (x%2==1)
    if (x<10)
        cout <<x;
else
    cout << "Wrong number";
```

Let say x=7,
Output:

7

Let say x=11,
Output:

Wrong Number

Correct!   Correct!

There is no syntax error, but this leads to a **logic error** due to the misinterpretation.

The **else** part actually belongs to the **second if** (if (x<10)), not to the first one

But, when x=12,
There is no output. This is **incorrect**.
It suppose to print "Wrong number"

Correction:

Related issues

- **Null statements** are statements that do nothing

  Example:

  ```
  if (x<3);
      cout <<"Yes";
  ```

  The semi-colon represents a null statement. Either the condition evaluates to true or false, there is nothing to do.

  The `cout` doesn't belong to `if` `statement`. The statement has already been ended up with semi-colon previously.

Example:

Let say x=5,
Output:

Let say x=1,
Output:

```
if (x<3)
    cout <<"Yes" <<endl;
else;
    cout <<"No" <<endl;
```

The semi-colon represents a null statement.

This `cout` doesn't belong to `else` part.

Simplifying `if` statements

- Simplifying conditions: ~~True~~ (handwritten: True)

Original statement

Simplified statement

```
if ( a != 0 )
    statement;
```

```
if ( a > 0 )
    statement;
```

```
if ( a < 0 )
    statement;
```

```
if ( a )
    statement;
```

```
if ( a == 0 )
    statement;
```

```
if ( !a )
    statement;
```

Simplifying `if` statements

- Example 1 : print a number only if it is an odd number

Original statement   *Simplified statement*

```
if ( n%2==1 )
    cout << n;
```
→
```
if ( n%2 )
    cout << n;
```

- Example 2: print a number only if it is an even number

Original statement   *Simplified statement*

```
if ( n%2==0 )
    cout << n;
```
→
```
if ( !(n%2) )
    cout << n;
```

Simplifying `if` statements

- Conditional Expressions:

(a) Logic Flow

$$a == b \; ? \; c-- \; : \; c++$$
(b) Code

Simplifying `if` statements

- Conditional Expressions:

If the condition is **true**, take the **value1**

If the condition is **false**, take the **value2**

Syntax:

```
condition ? value1 : value2
```

Example:

```
p = (p<5) ?  q + 1  : 5;
```

This statement means →

```
if (p<5)
     p = q + 1;
 else
     p = 5;
```

switch statement

- If there are many nested if/else statements, you may be able to replace them with a switch statement:

```cpp
if (letter_grade == 'A')
        cout << "Excellent!";
else if (letter_grade == 'B')
        cout << "Very good!";
else if (letter_grade == 'C')
        cout << "Good";
else if (letter_grade == 'D')
        cout << "Adequate";
else
        cout << "Fail";
```

```cpp
switch (letter_grade)
{
 case 'A' : cout <<"Excellent!";
            break;        to terminate the first cout

 case 'B' : cout <<"Very good!";
            break;

 case 'C' : cout <<"Good";
            break;

 case 'D' : cout <<"Adequate";
            break;

 default  : cout <<"Fail";
            break;
}
```

switch statement

```
switch (expression)
{
 case value1: statements_1;
               break;

 case value2 : statements_2;
               break;
   ...

 default : statements;
           break;
}
```

How the `switch` statement works?

1. Check the value of expression.

2. Is it equal to value1?
   - If yes, execute the statements_1 and break out of the switch.
   - If no, is it equal to value2? etc.

3. If it is not equal to any values of the above, execute the default statements and then break out of the switch.

switch statement

```
int value = 1;

                          evaluates to 1

switch (value)
{
 case 1: cout << "One";        Prints One
          break;
                         break out of the switch

  case 2: cout << "Two";
           break;

  default : cout << "Neither One nor Two";
           break;
}
```

it is equal to this case-value (i.e. 1==1). So, execute the statements of 'case 1'.

switch statement

Example 2:

```
int value = 1;

switch (value + 1)
{
  case 1: cout << "One";
          break;

  case 2: cout << "Two";
          break;

  default : cout << "Neither One nor Two";
            break;
}
```

this expression evaluates to **2**

it is not equal to this case-value (i.e. 2!=1). So, skip the statements of 'case 1' and move to the next case.

it is equal to this case-value (i.e. 2==2). So, execute the statements of 'case 2'.

Prints **Two**

break out of the switch

switch statement

Example 3:

```
int value = 5;

switch (value)
{
 case 1: cout << "One";
         break;

 case 2: cout << "Two";
          break;

 default : cout << "Neither One nor Two";
          break;
}
```

evaluates to 5

The switch expression (i.e. 5) is not equal to both cases (i.e 5!=1 and 5!=2). So, their statements are skipped.

When the 'default case' is reached, its statements are always executed.

break out of the switch

Prints **Neither One nor Two**

switch statement

*What if the **break** statement is not written?*

it is equal to this case-value (i.e. 1==1). So, execute the statements of the 'case 1'.

```
int value = 1;                    evaluates to 1

switch (value)
{
 case 1: cout << "One\n";         Prints One

                                  No break statement here. So,
                                  no break out and move to the
                                  next line.

 case 2: cout << "Two\n";         Prints Two
         break;
                                  break out of the switch

 default : cout << "Neither One nor Two\n";
         break;
}
```

switch statement

- The switch expression must be of integral type (i.e. **int,char,bool**).
- The following examples would be an error

```
void main()
{
 float point=4.0;
 int mark;

 switch (point)
 {
   case 4    : mark = 100;
             break;

   case 3.7 : mark = 80;
             break;

   default  : mark = 0;
             break;
 }

}
```

Error! The switch expression cannot be a **float** value

```
void main()
{
 char name[]="Ali";
 int mark;

 switch (name)
 {
   case "Ali"   : mark=95;
             break;

   case "Aminah": mark=90;
             break;

   default      : mark=50;
             break;
 }
}
```

Error! The switch expression cannot be a **string** value

`switch` statement

- The case-value must be a constant (literal, memory or defined constant)
- The following example would be an error

```
void main()
{
 #define DEFINE 1
 const int const2=2;
 int var3 = 3;   variable
 int value;

 switch (value)
 { case 0        : cout << "Four";
                     break;

   case DEFINE    : cout << "One";
                     break;

   case const2    : cout << "Two";
                     break;

   case var3      : cout << "Three";
                     break;
 }
}
```

a literal is OK

a defined constant is OK

a memory constant is OK

Error! case-value cannot be a variable

Translating flowchart to C++ code

Pattern 1

```
if (condition)
{
 statement;
}
```
Example 1: *Printing a number only if it is a negative*
```
if (n<0)
{
 cout << n;
}
```

Translating flowchart to C++ code

Pattern 2

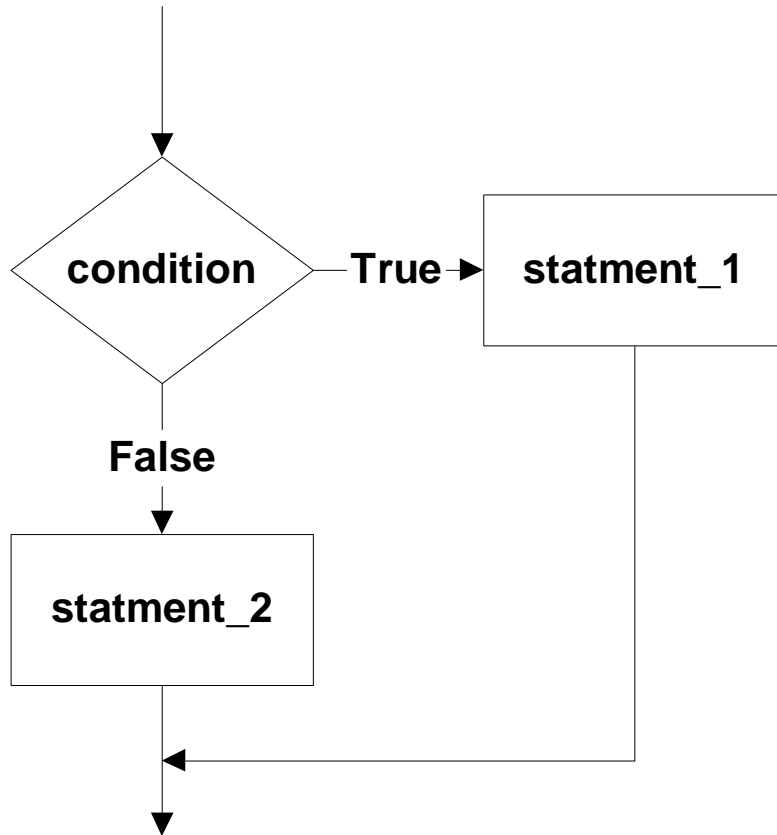

```cpp
if (condition)
{
 statement_1;
}
else
  {
    statement_2;
  }
```

Example 2: *If two numbers (p and q) are equivalent reset them to zero, otherwise exchange or swap their value each other and then print the new values.*

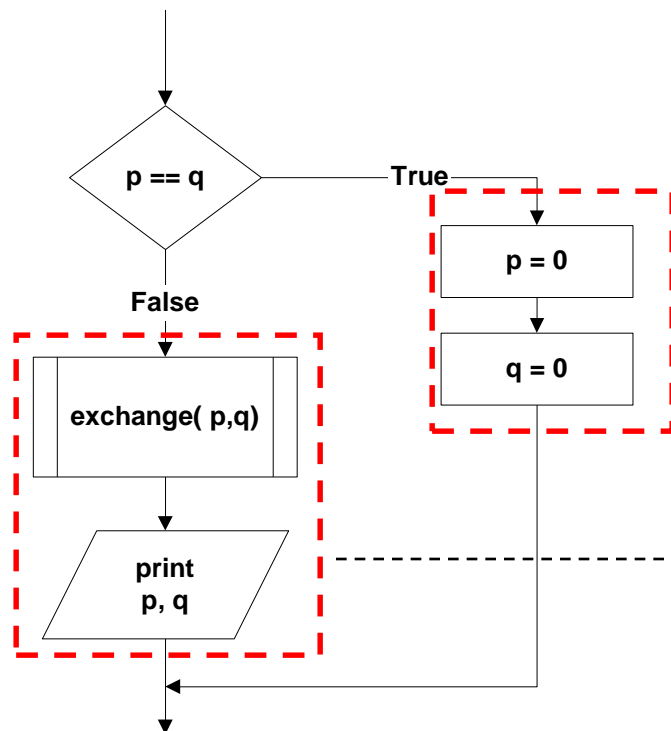

```
if (p==q)
{
  p = 0;
  q = 0;
}
else
{
  exchange(&p,&q);
  cout << p << q;
}
```

Translating flowchart to C++ code

Pattern 3

```cpp
if (condition_1)
{
  statement_1;
}
else if (condition_2)
{
  statement_2;
}
      |
      |
      |
      |
else if (condition_n)
{
  statement_n;
}
else
{
  statement_m;
}
```

Example 3: *Identifying the grade of a score*

```cpp
if (score > 90)
{
    grade  = 'A';
}
else if (score > 75)
{
    grade = 'B';
}
else if (score > 60)
{
    grade = 'C';
}
else if (score > 50)
{
    grade = 'D';
}
else
{
    grade = 'F';
}
```

Pattern 4

- *The conditions must be in this form:*

expression == value

```
switch (expr)
{
   case val_1 :  statement_1;
                 break;

   case val_2 :  statement_2;
                 break;
          |
          |
          |
          |
          |
   case val_n :  statement_n;
                 break;

   default:      statement_m;
                 break;
}
```

Translating flowchart to C++ code

Example 4: *Printing the description of a grade.*

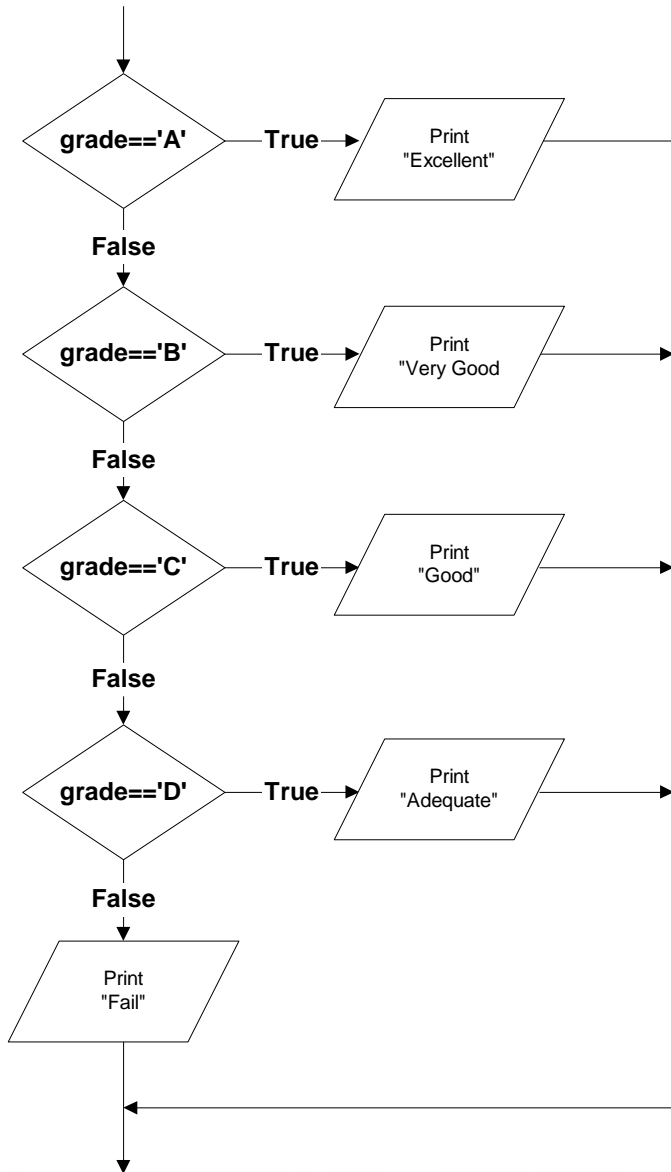

```cpp
switch (grade)
{
    case 'A' : cout << "Excellent!";
               break;

    case 'B' : cout << "Very good!";
               break;

    case 'C' : cout << "Good";
               break;

    case 'D' : cout << "Adequate";
               break;

    default  : cout << "Fail";
               break;
}
```

Loop / Repetition

- The main idea of a loop is to repeat an action or a series of actions.
The concept of a loop

Loops

- But, when to stop looping?
- In the following flowchart, the action is executed over and over again. It never stop – This is called an infinite loop
- Solution – put a condition to tell the loop either continue looping or stop.

An action or a series of actions
Loops

- A loop has two parts – body and condition

- Body – a statement or a block of statements that will be repeated.

- Condition – is used to control the iteration – either to continue or stop iterating.

```
        ↓
    ┌───┘
    │   ↓
    │  ┌──────────┐
True│  │   Body   │
    │  └──────────┘
    │        ↓
    │   ╱─────────╲
    └──│ Condition │
        ╲─────────╱
             ↓
           False
             ↓
```
Types of loop

- Two forms of loop – pretest loop and post-test loop.

- Pretest loop
  - the condition is tested first, before we start executing the body.

  - The body is executed if the condition is true.

  - After executing the body, the loop repeats

Pretest loop

Condition

Here must be a "True"

True

Body

False
Types of loop

- **Post-test loop**
  - the condition is tested later, after executing the body.

  - If the condition is true, the loop repeats, otherwise it terminates.

  - The body is always executed at least once.

Post-test loop

True

Body

Condition

The iterating part must be a "True"

False
Parts of a loop

- Beside the body and condition, a loop may have two other parts – Initialization and Updating

Pretest loop

Initialization → Condition → (True) → Body → Updating → (loops back to Condition) / (False) → exit

Post-test loop

Initialization → Body → Updating → Condition → (True, loops back to Body) / (False) → exit
Parts of a loop

- **Initialization**
  - is used to prepare a loop before it can start –usually, here we initialize the condition

  - The initialization must be written outside of the loop – before the first execution of the body.

- **Updating**
  - is used to update the condition

  - If the condition is not updated, it always true => the loop always repeats – an infinite loop

  - The updating part is written inside the loop – it is actually a part of the body.
Parts of a loop

Example: *These flowcharts print numbers 10 down to 1*

Pretest loop

n=10

is n>0?

True

Print n

n = n -1

False

Post-test loop

n=10

Print n

n = n -1

is n>0?

True

False
Initialize n before start the loop

Every time the loop repeats, n is updated
Loop statements

- C++ provides three loop statements:
C++ loop constructs

while statement

```
while (Condition)
{
    Repeated_Actions;
}
```
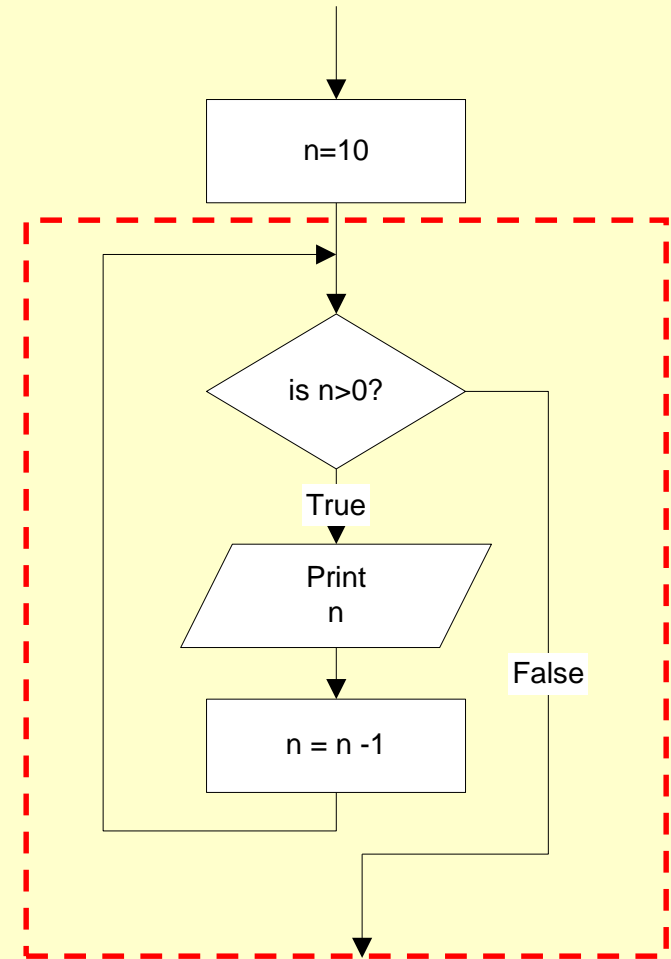

while flowchart

while statement

Example: *This* `while` *statement prints numbers 10 down to 1*

Note that, the first line (`n=10`) is actually not a part of the loop statement.

```
n=10;
while (n>0)
{
  cout << n <<" ";
  n=n-1;
}
```
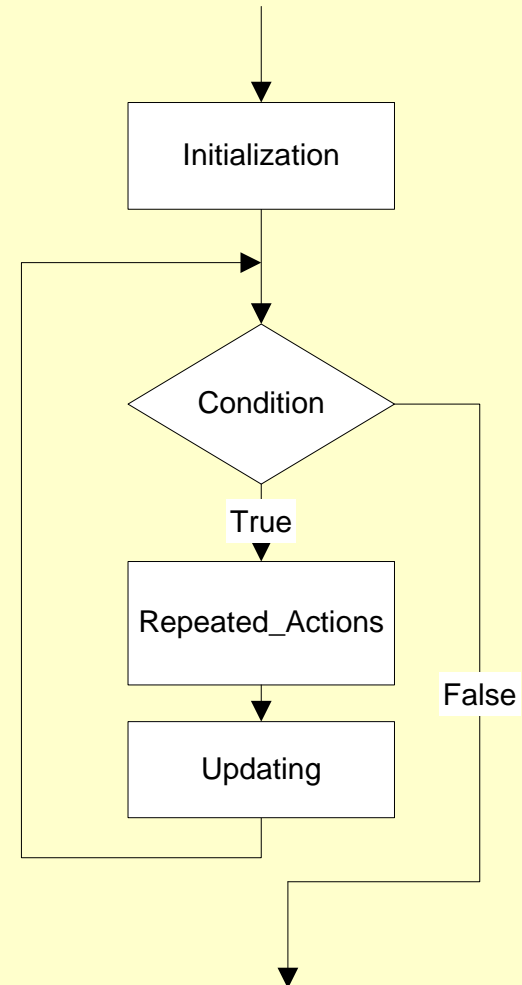

for statement

can be here

stay the ;

```
for (Initialization; Condition; Updating)
{
    Repeated_Actions;
}
```
can be here

single statement can ignore braces

for flowchart

- Initialization
- Condition
  - True
    - Repeated_Actions
    - Updating
  - False

Example: *This `for` statement prints numbers 10 down to 1*

```
for (n=10; n>0; n=n-1)
{
  cout << n <<" ";
}
```
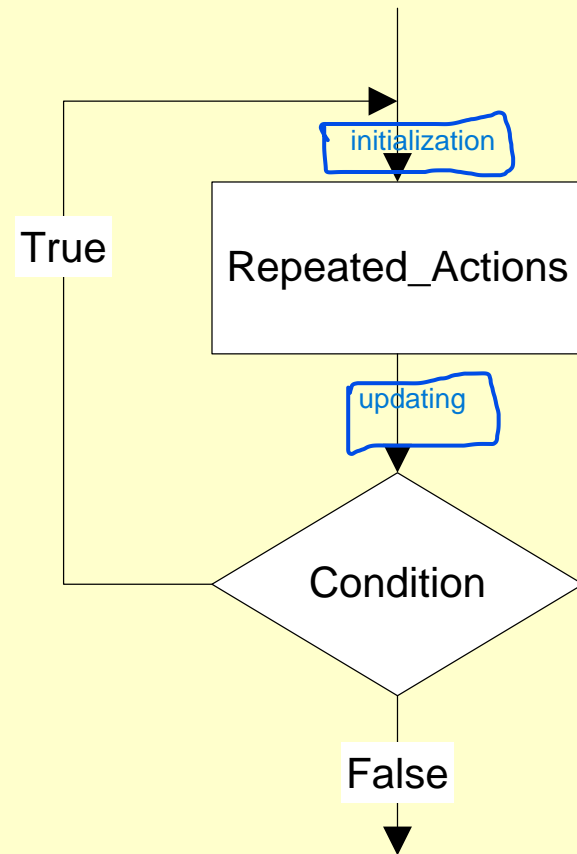

for VS. while statements

Comparing `for` and `while` loops

do…while statement

```
do
{
    Repeated_Actions;
} while (Condition);
```

initialization

True

Repeated_Actions

updating

Condition

False

do…while statement

Example: This `do…while` *statement prints numbers 10 down to 1*

Note that, the first line (`n=10`) is actually not a part of the loop statement.

```
n=10;
do
{
    cout << n << " ";
    n=n-1;
} while (n>0);
```

- If the body part has only one statement, then the bracket symbols, { } may be omitted.

- Example: These two `for` statements are equivalent.
```
for (n=10; n>0; n=n-1)
{
 cout << n;
}
```

```
for (n=10; n>0; n=n-1)
  cout << n;
```

Jump statements

- You have learn that, the repetition of a loop is controlled by the loop condition.

- C++ provides another way to control the loop, by using jump statements.

- There are four jump statements:

```
                    ┌──────────────┐
                    │    Jump      │
                    │  Statements  │
                    └──────────────┘
        ┌───────────────┬──────┴───────┬───────────────┐
   ┌─────────┐    ┌──────────┐   ┌──────────┐   ┌──────────┐
   │  break  │    │ continue │   │  return  │   │   goto   │
   └─────────┘    └──────────┘   └──────────┘   └──────────┘
```

Breaking Out of a Loop

- Can use **`break`** to terminate execution of a loop

- Use sparingly if at all – makes code harder to understand

- When used in an inner loop, terminates that loop only and returns to the outer loop

break statement

- It causes a loop to terminate

Example:

```
for (n=10; n>0; n=n-1)
{
 if (n<8) break;
 cout << n << " ";
}
```

10 9 8

break statement

break an inner loop

The `continue` Statement

- Can use **`continue`** to go to end of loop and prepare for next repetition
  - **`while`** and **`do-while`** loops go to test and repeat the loop if test condition is true
  - **`for`** loop goes to update step, then tests, and repeats loop if test condition is true
- Use sparingly – like **`break`**, can make program logic hard to follow

`continue` statement

- In `while` and `do…while` loops, the `continue` statement transfers the control to the loop condition.

- In `for` loop, the `continue` statement transfers the control to the updating part.
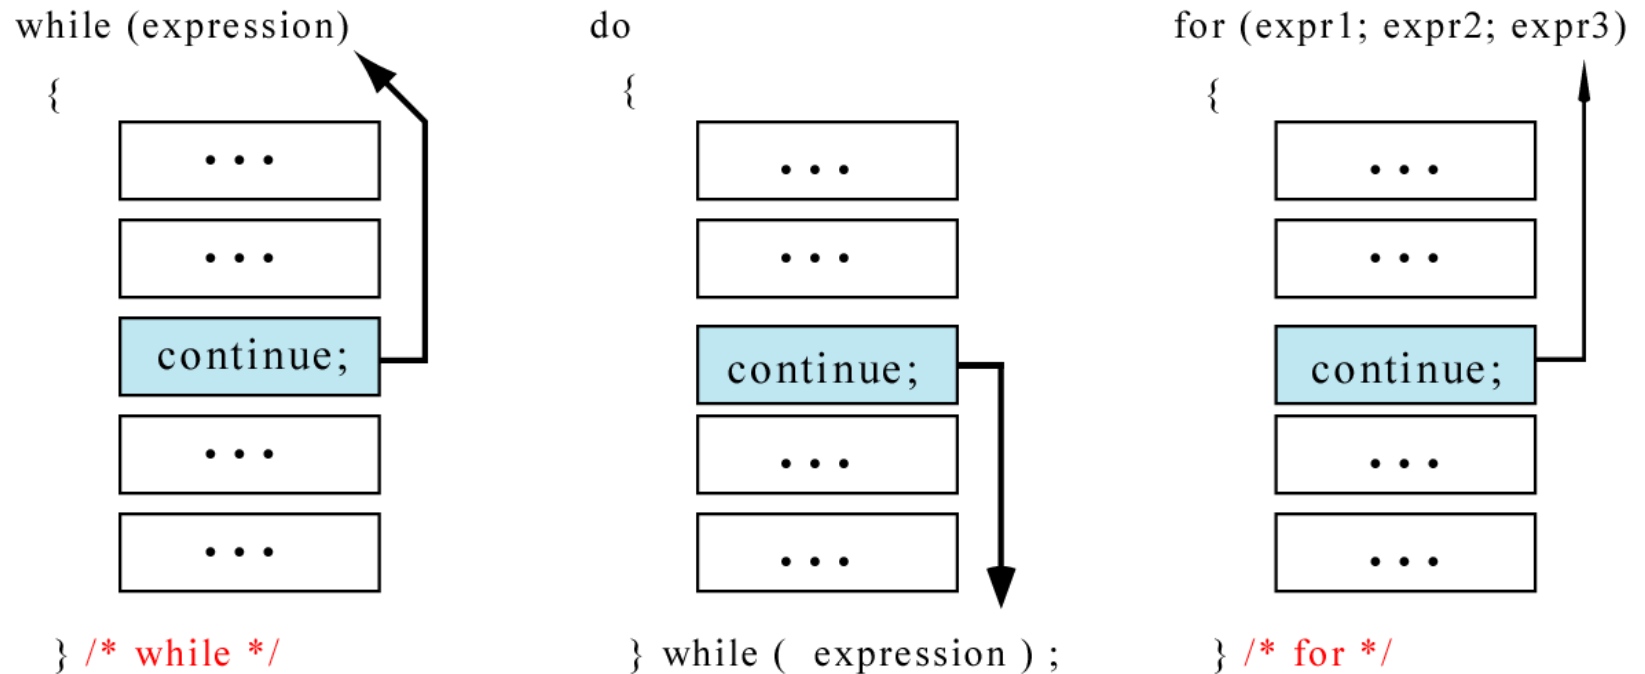

The *continue* statement

continue statement

Example:

10 8 6 4 2

```
for (n=10; n>0; n=n-1)
{
 if (n%2==1) continue;
 cout << n <<" ";
}
```

continue statement

Example:

10 9 9 9 .....

```
n = 10;
while (n>0)
{
 cout << n << " ";
 if (n%2==1) continue;
 n = n -1;
}
```

`return` statement

- You will learn this statement in Chapter 4 – Function.
- It causes a function to terminate.

Example:

```
void print_numbers()
{ int n=10;
  int i;

  while (n>0)
  {
    for (i=n;i>0; i--)
    {
      if (i%2==1) continue;

      if (i%4==0) break;

      if (n==6) return;

      cout <<i <<" ";
    }
    cout << endl;
    n=n-1;
  }
}
```

10

6

The **continue** statement transfers control to the updating part (*i--*)

The **break** statement terminates the **for** loop.

The **return** statement terminates the **function** and returns to the caller.

return statement

- When to use `return`?
- *Example:* the following functions are equivalent

```
float calc_point(char grade)
{
 float result;

 if (grade=='A') result = 4.0;
 else if (grade=='B') result = 3.0;
 else if (grade=='C') result = 2.5;
 else if (grade=='D') result = 2.0;
 else result = 0.0;

 return result;
}
```

```
float calc_point(char grade)
{
 if (grade=='A') return 4.0;
 if (grade=='B') return 3.0;
 if (grade=='C') return 2.5;
 if (grade=='D') return 2.0;
 return 0.0;
}
```

type is match

The *else* part of each *if* statement may be omitted. It has never been reached.

return statement

```
float calc_point3(char grade)
{
 float result;

 switch (grade)
 {
   case 'A': result = 4.0;
             break;

   case 'B': result = 3.0;
             break;

   case 'C': result = 2.5;
             break;

   case 'D': result = 2.0;
             break;

   default:  result =0.0;
 }

 return result;
}
```

```
float calc_point4(char grade)
{
 switch (grade)
 {
   case 'A': return 4.0;

   case 'B': return 3.0;

   case 'C': return 2.5;

   case 'D': return 2.0;
 }
 return 0.0;
}
```
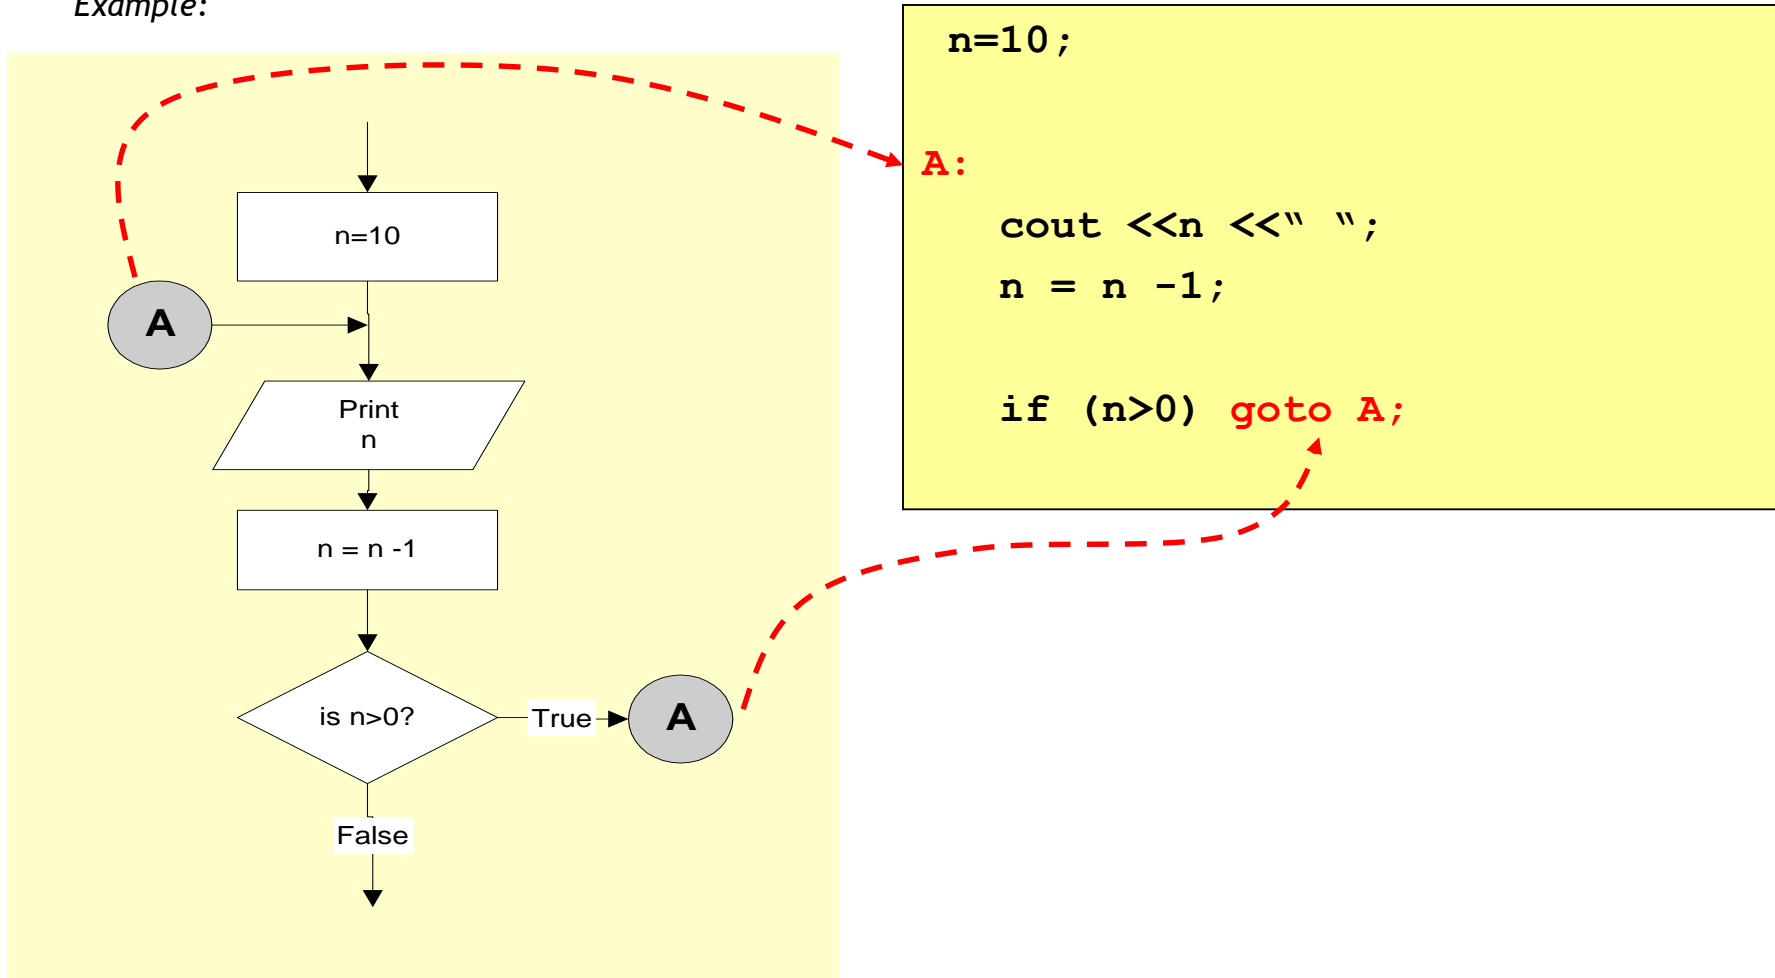

The *break* statement of each *case* may be omitted. It has never been reached.
break from switch also f(x)

goto statement

- It is used to translate connector symbols – jump to another part inside a program.
- But, it is not recommended to use - it may cause unstructured programs.

Example:

```
n=10;

A:

    cout <<n <<" ";
    n = n -1;

    if (n>0) goto A;
```

Translating flowchart to C++ code

Pattern 1

Here must be a "False"

condition

Here must be a "True"

True

Repeated_Actions

False

```cpp
while (condition)
{
  Repeated_Actions;
}
```
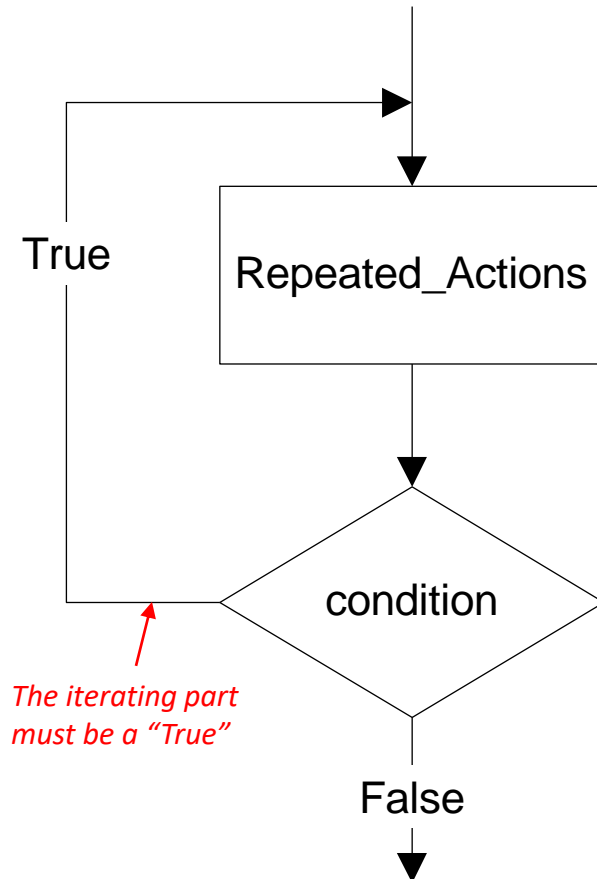

Example: *Calculate the average of odd numbers 1 to 9*

```cpp
sum = 0;
i=1;
while (i<11)
{
  sum = sum + i;
  i = i + 2;
}
avrg = sum/5.0;
```
Pattern 2

True

Repeated_Actions

condition

The iterating part must be a "True"

False

```cpp
do
{
  Repeated_Actions;
} while(condition);
```

Translating flowchart to C++ code

Example: *Prints numbers 1 to 10*

```cpp
i=1;
do
{
 cout <<i <<endl;
 i = i + 1;
} while (i<11);
```

Translating flowchart to C++ code
Pattern 3

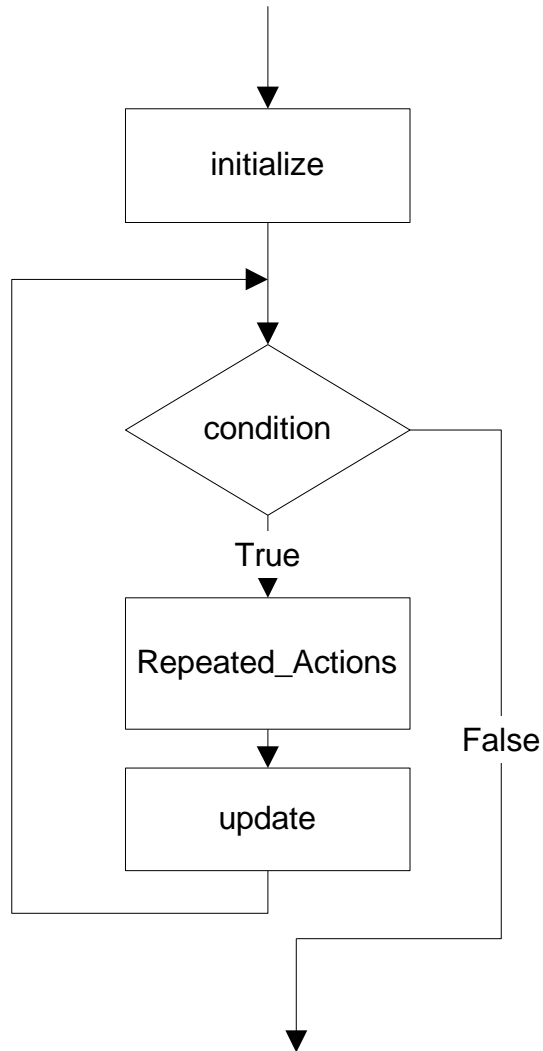

```
for (initialize; condition; update)
{
 Repeated_Actions;
}
```

or

```
initialize;
while (condition)
{
 Repeated_Actions;
 update;
}
```

Translating flowchart to C++ code

Example: *Print the total of numbers 1 to 10*

```
total = 0;
for (i=1; i<11; i++)
{
 total = total + i;
}
cout <<total;
```

or

```
total = 0;
i=1;
while (i<11)
{
 total = total + i;
 i++;
}
cout <<total;
```
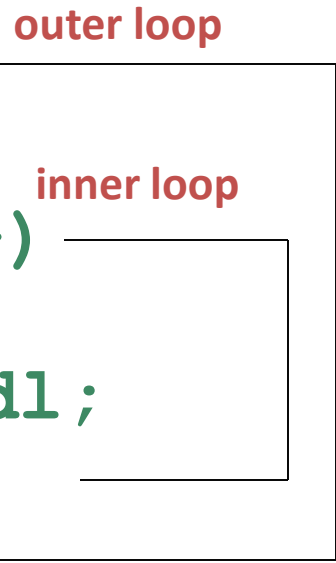

Deciding Which Loop to Use

- `while`: pretest loop (loop body may not be executed at all)

- `do-while`: post test loop (loop body will always be executed at least once)

- `for`: pretest loop (loop body may not be executed at all); has initialization and update code; is useful with counters or if precise number of repetitions is known

Nested Loops

- A nested loop is a loop inside the body of another loop

- Example:

outer loop

inner loop

```cpp
for (row=1; row<=3; row++)
{
    for (col=1; col<=3; col++)
    {
        cout << row * col << endl;
    }
}
```

Notes on Nested Loops

- Inner loop goes through all its repetitions for each repetition of outer loop

- Inner loop repetitions complete sooner than outer loop

- Total number of repetitions for inner loop is product of number of repetitions of the two loops. In previous example, inner loop repeats 9 times

- How many times the outer loop is executed? How many times the inner loop is executed? What is the output?

```cpp
#include <iostream>
using namespace std;
int main()
{    int x, y;
     for(x=1;x<=8;x+=2)
       for(y=x;y<=10;y+=3)
         cout<<"\nx = " <<x << "   y = "<<y;
     return 0;
}
```
